```

Floral abundance vs field management (%grass+forb)

Use cumulative link model aka ordinal logistic regression because bombus-relevant floral abundance has:

- discrete levels (0-5 scale) representing binned counts of blooms
- ordered categories (higher numbers represent more blooms)
- unequal intervals between categories

Steps

1) Tried running CLM with different random effect structures (full = 1|area/site/plot) then compared AIC values to determine best model.

- determined that model without random effect had best fit

```r
floral_full <- clmm(as.factor(bombus_floral_abun) ~ grass_forb_perc_scaled +
                        julian.date_scaled +
                        (1|area/site_id/plot_id),
                      link = "logit",
                      data = field_data)

floral_noArea <- clmm(as.factor(bombus_floral_abun) ~ grass_forb_perc_scaled +
                        julian.date_scaled +
                        (1|site_id/plot_id),
                      link = "logit",
                      data = field_data)

#floral_plotOnly <- clmm(as.factor(bombus_floral_abun) ~ grass_forb_perc_scaled +
```

```
 #                        julian.date_scaled +
  #                       (1|plot_id),
   #                    link = "logit",
    #                   data = field_data)
##can't use since there are only 2 levels

floral_siteOnly <- clmm(as.factor(bombus_floral_abun) ~ grass_forb_perc_scaled +
                         julian.date_scaled +
                         (1|site_id),
                       link = "logit",
                       data = field_data)

floral_AreaPlot <- clmm(as.factor(bombus_floral_abun) ~ grass_forb_perc_scaled +
                         julian.date_scaled +
                         (1|area/plot_id),
                       link = "logit",
                       data = field_data)
floral_noRE <- polr(as.factor(bombus_floral_abun) ~ grass_forb_perc_scaled +
                         julian.date_scaled,
                       method = "logistic",
                       data = field_data)

#compare models AIC
AIC(floral_full, floral_noArea, floral_siteOnly, floral_AreaPlot, floral_noRE)
```

```
##                 df      AIC
## floral_full      9 441.1757
## floral_noArea    8 439.1757
## floral_siteOnly  7 437.1757
## floral_AreaPlot  8 439.1757
## floral_noRE      6 435.1757
```

```
##shows that model without random effect has best fit
```

2) Compare AIC between model with and without cover_type as a covariate.

- determined that model without cover type as covariate was better

```
floral_noRE_cover <- polr(as.factor(bombus_floral_abun) ~ grass_forb_perc_scaled +
                            cover_type +
                         julian.date_scaled,
                       method = "logistic",
                       data = field_data)

AIC(floral_noRE_cover, floral_noRE)
```

```
##                   df      AIC
## floral_noRE_cover  7 437.1425
## floral_noRE        6 435.1757
```

```r
##not including cover is better
```

3) Run final model and look at output

```r
floral_noRE <- polr(as.factor(bombus_floral_abun) ~ grass_forb_perc_scaled +
                         julian.date_scaled,
                       method = "logistic",
                       data = field_data)

summary(floral_noRE)
```

```

Findings

No significant effect of either grass+ forb% or julian date.

Rodent burrows vs field management (%grass+forb)

Since the number of rodent burrows was count data, I knew I had to use either a poisson or negative binomial GLM family. I started with the simplest family (poisson) first.

Steps

1) Try different random effect structures in the poisson. Compare models using likelihood ratio tests to determine best random effect structure.

- best fit = 1|site_id/plot_id –> **area not included**

```r
burrows_full <- glmmTMB(num_burrows ~ grass_forb_perc_scaled +
                             julian.date_scaled +
                             (1|area/site_id/plot_id),
                           family = poisson,
                           data = field_data)

burrows_noArea <- glmmTMB(num_burrows ~ grass_forb_perc_scaled +
                             julian.date_scaled +
                             (1|site_id/plot_id),
                           family = poisson,
                           data = field_data)

burrows_plotOnly <- glmmTMB(num_burrows ~ grass_forb_perc_scaled +
                             julian.date_scaled +
                             (1|plot_id),
                           family = poisson,
                           data = field_data)

burrows_siteOnly <- glmmTMB(num_burrows ~ grass_forb_perc_scaled +
                             julian.date_scaled +
                             (1|site_id),
                           family = poisson,
                           data = field_data)

burrows_AreaPlot <- glmmTMB(num_burrows ~ grass_forb_perc_scaled +
                             julian.date_scaled +
                             (1|area/plot_id),
                           family = poisson,
                           data = field_data)

#compare models using maximum likelihood test
anova(burrows_full, burrows_noArea, burrows_plotOnly, burrows_siteOnly, burrows_AreaPlot)
```

```
## Data: field_data

```

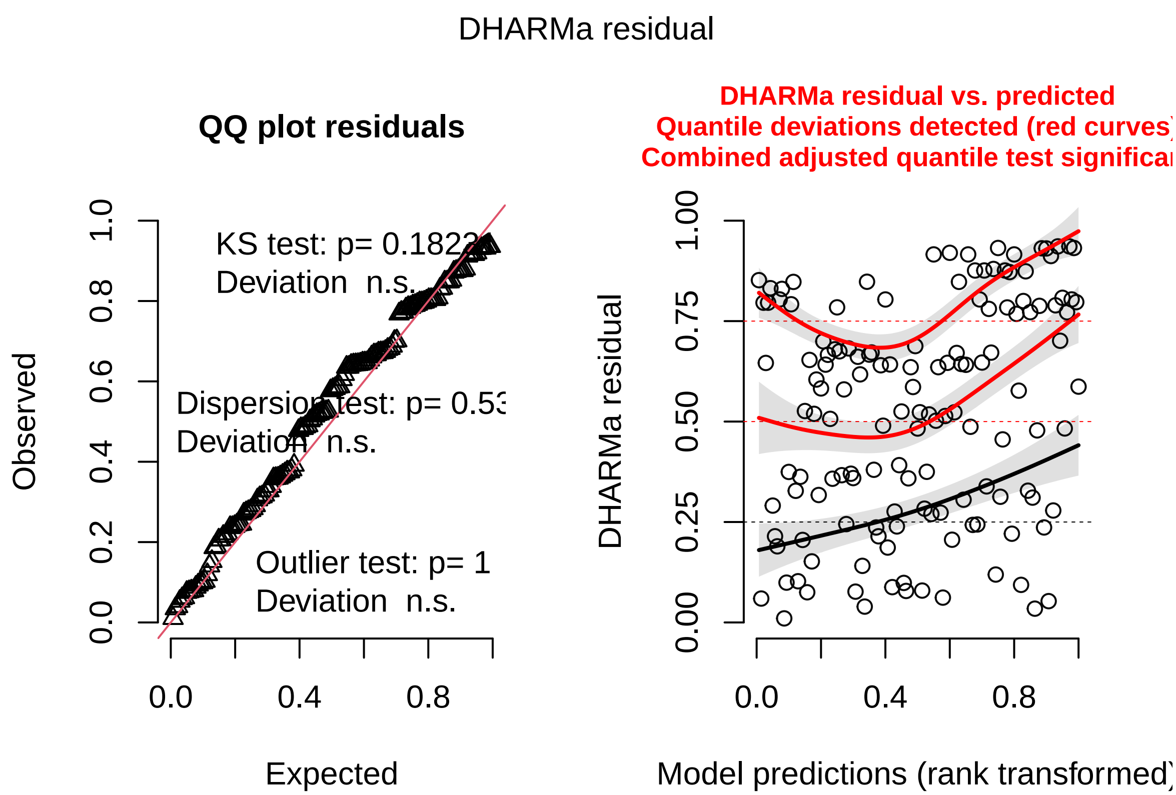
```r
##results tells us the burrows_noArea is best model (lowest AIC)
```

2) Check diagnostics of the model using DHARMa package.

- Combined adjusted quantile test significant

```r
#simulate residuals
residuals_burrows_noArea <- simulateResiduals(fittedModel = burrows_noArea, plot = TRUE)
```



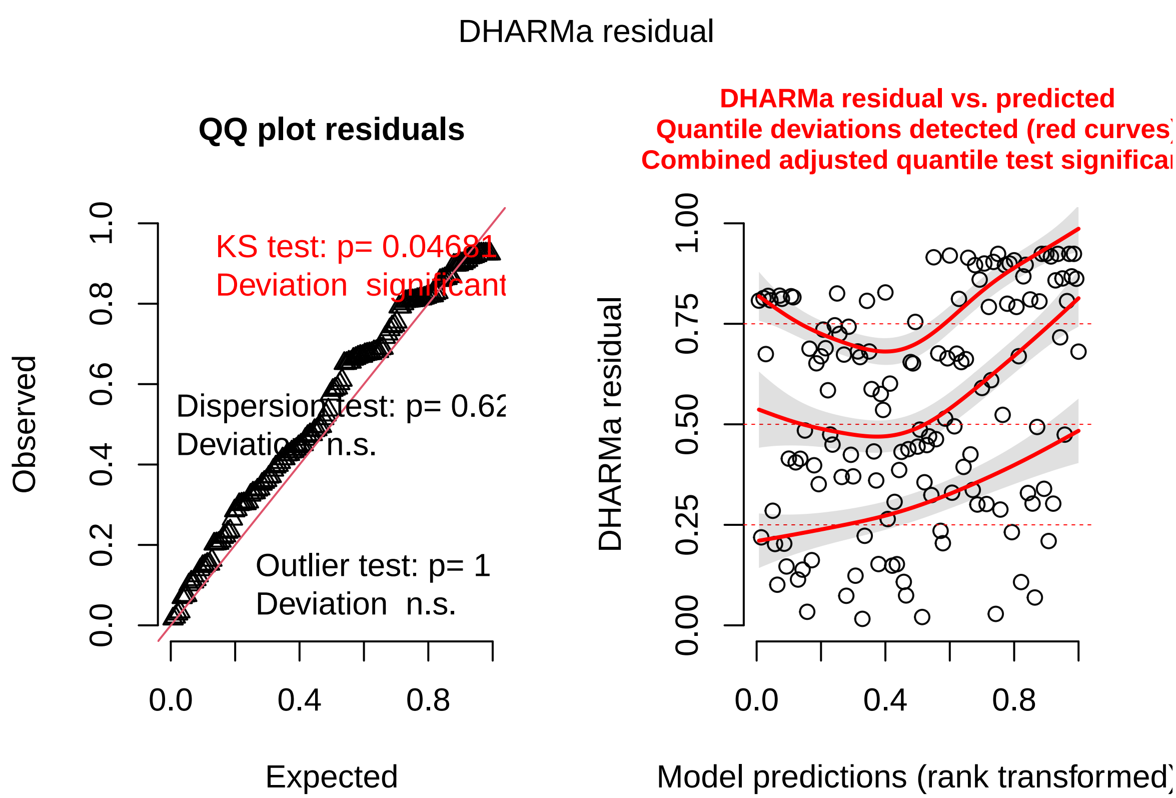
3) Try negative binomial instead and check diagnostics.

- Combined adjusted quantile test still significant.

```r
burrows_noArea_negBin <- glmmTMB(num_burrows ~ grass_forb_perc_scaled +
                              julian.date_scaled +
                              (1|site_id/plot_id),
                           family = nbinom1, #use nbinom1 since nbinom2 doesn't converge
                           data = field_data)

#simulate residuals
residuals_burrows_noArea_negBin <- simulateResiduals(fittedModel = burrows_noArea_negBin, plot = TRUE)
```

```
## Warning in newton(lsp = lsp, X = G$X, y = G$y, Eb = G$Eb, UrS = G$UrS, L = G$L,
## : Fitting terminated with step failure - check results carefully
```

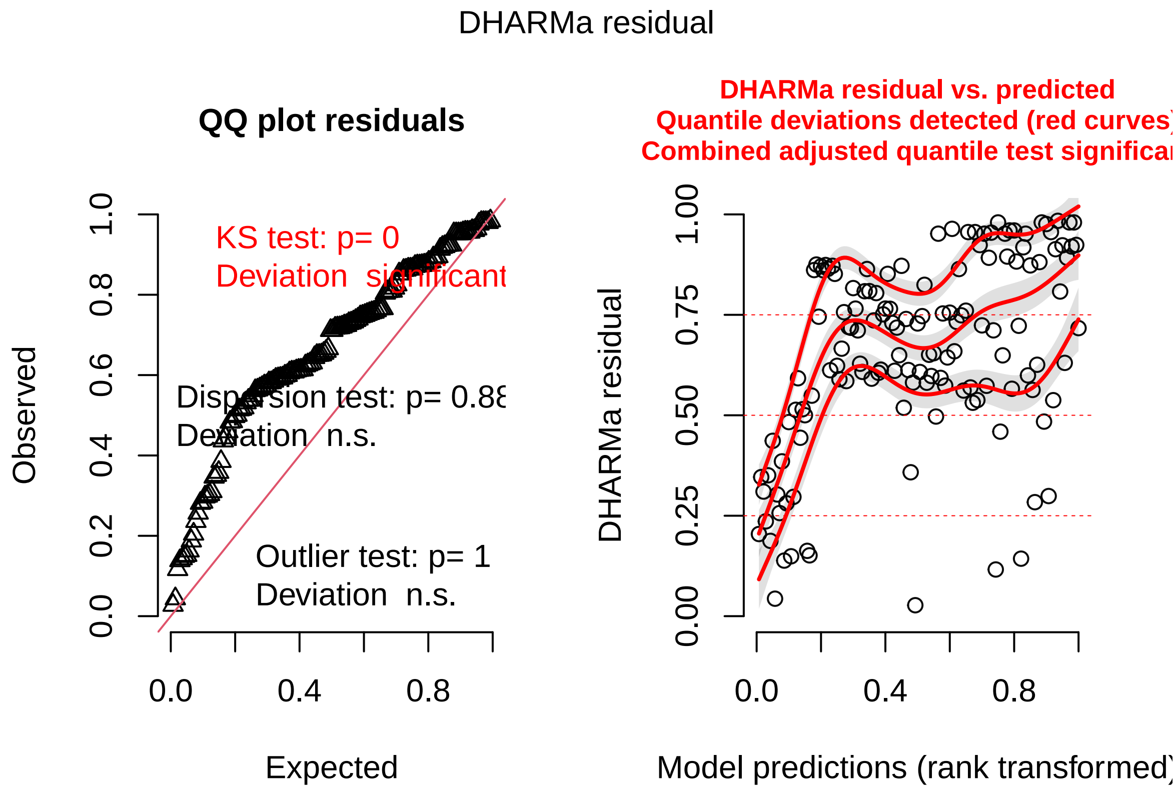


4) Try zero-inflated poisson and check diagnostics.

- KS test and combined adjusted quantile test still significant.

```r
burrows_zi_pois <- glmmTMB(num_burrows ~ grass_forb_perc_scaled +
                              julian.date_scaled +
                              (1|site_id/plot_id),
                           ziformula = ~ grass_forb_perc_scaled +
                              julian.date_scaled +
                              (1|site_id/plot_id), # zero-inflation model
                           family = poisson,
                           data = field_data)
```

```r
#simulate residuals
residuals_burrows_zi <- simulateResiduals(fittedModel = burrows_zi_pois, plot = TRUE)
```

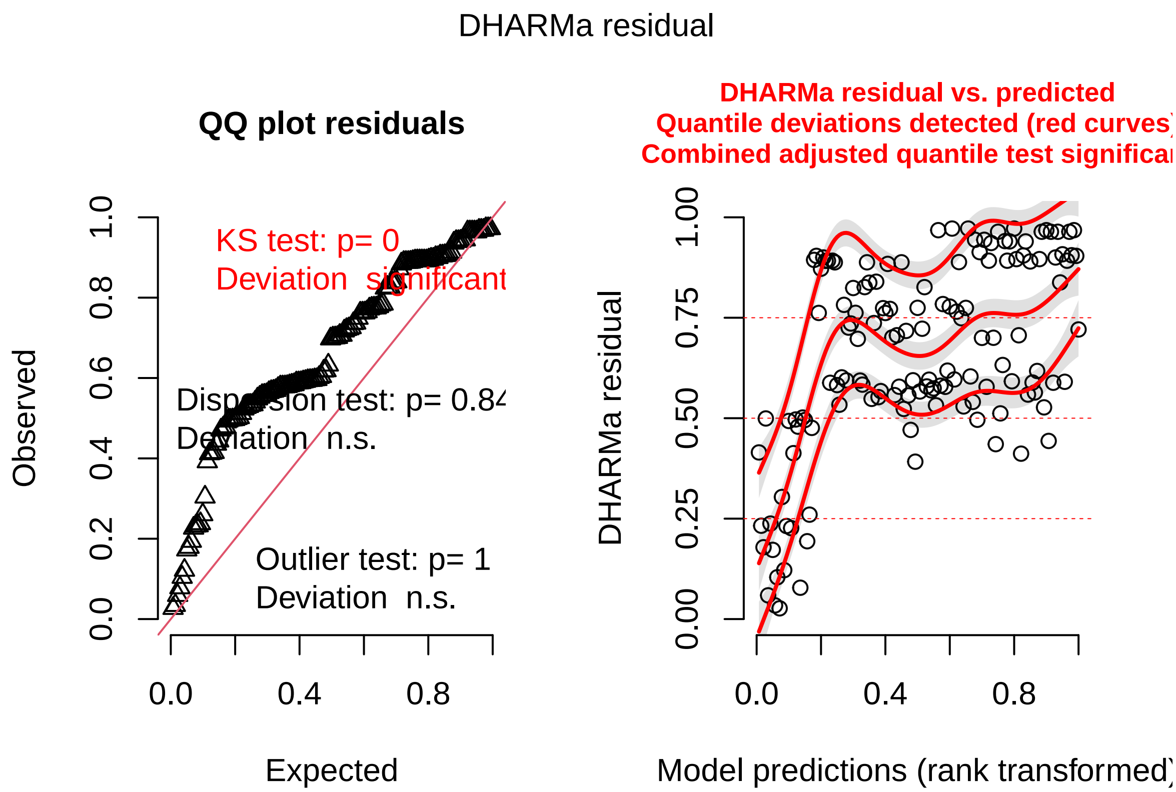


5) Try zero-inflated negative binomial and check diagnostics.

- KS test and combined adjusted quantile test still significant.

```r
burrows_zi_nbin <- glmmTMB(num_burrows ~ grass_forb_perc_scaled +
                             julian.date_scaled +
                             (1|site_id/plot_id),
                           ziformula = ~ grass_forb_perc_scaled +
                             julian.date_scaled +
                             (1|site_id/plot_id), # zero-inflation model
                           family = nbinom2,
                           data = field_data)

#simulate residuals
residuals_burrows_zi_nbin <- simulateResiduals(fittedModel = burrows_zi_nbin, plot = TRUE)
```



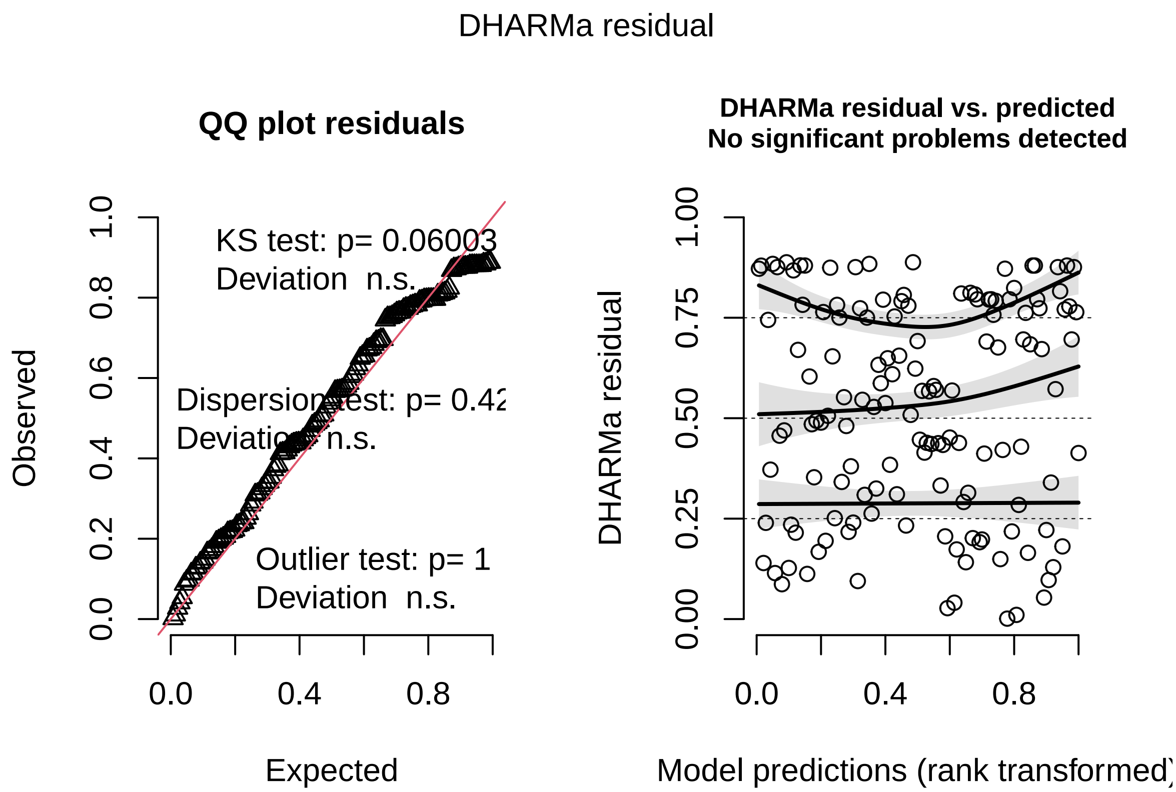
```
#signficant KS test and combined adjusted quantile test
```

6) Stick with poisson but try adding cover_type as an additional covariate and check diagnostics.

- none of the tests were significant! –> good to keep this one

```
burrows_pois_cover <- glmmTMB(num_burrows ~ grass_forb_perc_scaled +
                                         julian.date_scaled +
                                         cover_type +
                               (1|site_id/plot_id),
                             family = poisson,
                             data = field_data)

#simulate residuals
residuals_burrows_pois_cover <- simulateResiduals(fittedModel = burrows_pois_cover, plot = TRUE)
```



```r
summary(burrows_pois_cover)
```

```

```

Findings

Neither grass + forb % nor julian date had significant effects on rodent burrow abundance. However, cover type showed a marginally insignificant trend (p=0.149), where grassy sites had a higher abundance of burrows.

Number of nest-searching queens vs flowers, rodents, and field management technique

Start by plotting a zero-inflated poisson, since # of nest-searching queens is count data with a lot of zeros. I added bee_season_type as a covariate, since during my exploratory data analyses I saw that there was only a significant different in nest-searching queens among grassy vs bare sites during nesting season.

Steps

1) Plot zero-inflated poisson and check diagnostics.

- No significant problems detected.

```
nsq_zeroPois <- glmmTMB(nest_searching_queens ~ grass_forb_perc_scaled +
                    bombus_floral_abun_scaled +
                    num_burrows_scaled +
                    bee_season_type,
                  ziformula = ~ grass_forb_perc_scaled +
                    bombus_floral_abun_scaled +
                    num_burrows_scaled +
                    bee_season_type,  # zero-inflation model
                  family = poisson, #poisson
                  data = field_data)

residuals_nsq_zeroPois <- simulateResiduals(fittedModel = nsq_zeroPois, plot = TRUE)
```

Findings

In conditional model (modelling abundance of nest-searching queens):

- no significant effect of grass+forb%, floral abundance, bee season
- significant positive effect of number of burrows

In zero-inflation model (modelling presence/absence of nest-searching queens):

- no significant effect of floral abundance
- Significant effect of grass+forb% (less likely to be absent with more grass/forb), number of burrows (more likely to be absent with more burrows), bee season (more likely to be absent during worker season than nest-searching season).

Interestingly, the number of rodent burrows is associated with more bombus nest-searching in the conditional model, but the number of rodent burrows is associated with more structural zeros in the zero-inflation model. This means that if a site is suitable for nesting, more rodent burrows is associated with more bombus nest-searching. However, in some cases, rodent burrows may signal inhospitable habitat conditions for bumble bees.

Number of workers vs nest-searching queens, floral abundance, rodent burrows.

Go through similar model selection steps as for the rodent burrow model.

Steps

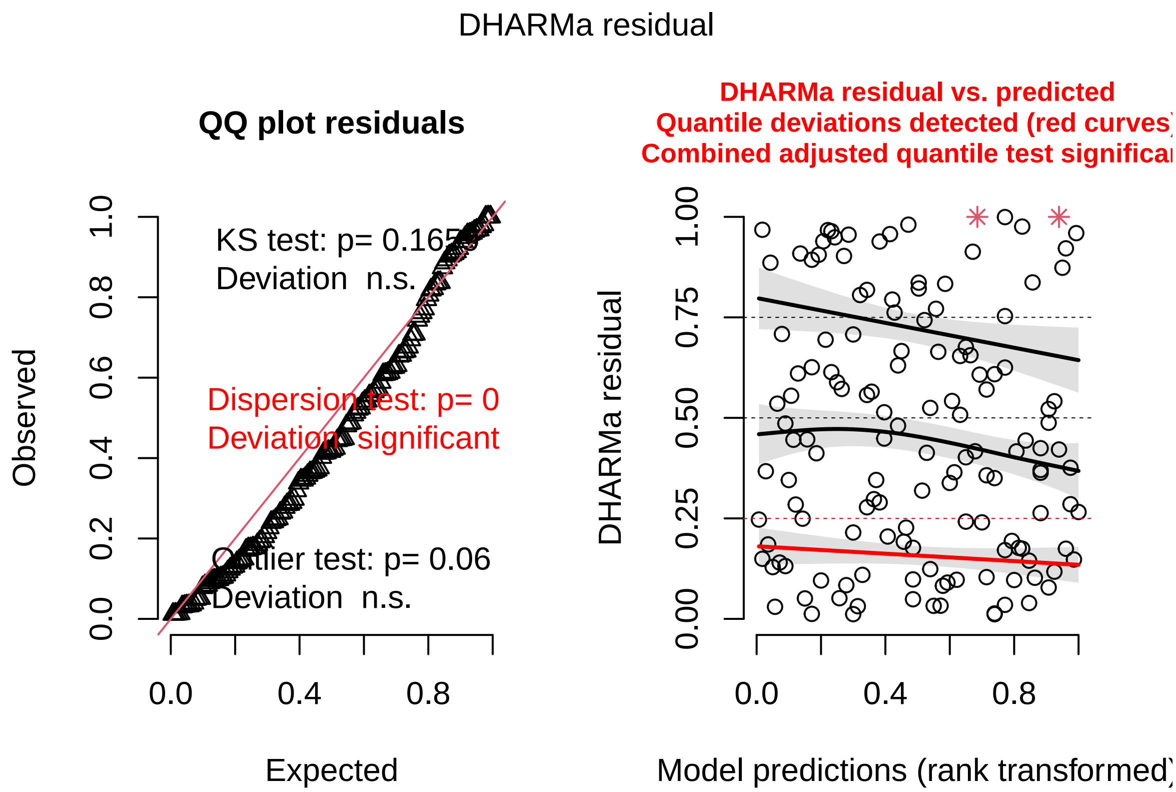
1) Plot poisson model and check diagnostics.

- Residual plots show that there is significant overdispersion

```
worker_lm_pois <- glmmTMB(workers ~ nest_searching_queens_scaled +
                        bombus_floral_abun_scaled +
                        num_burrows_scaled +
                        bee_season_type,
                      family = poisson,
                      data = field_data
```

```
                    )

#simulate residuals
residuals_workers_pois <- simulateResiduals(fittedModel = worker_lm_pois, plot = TRUE)
```

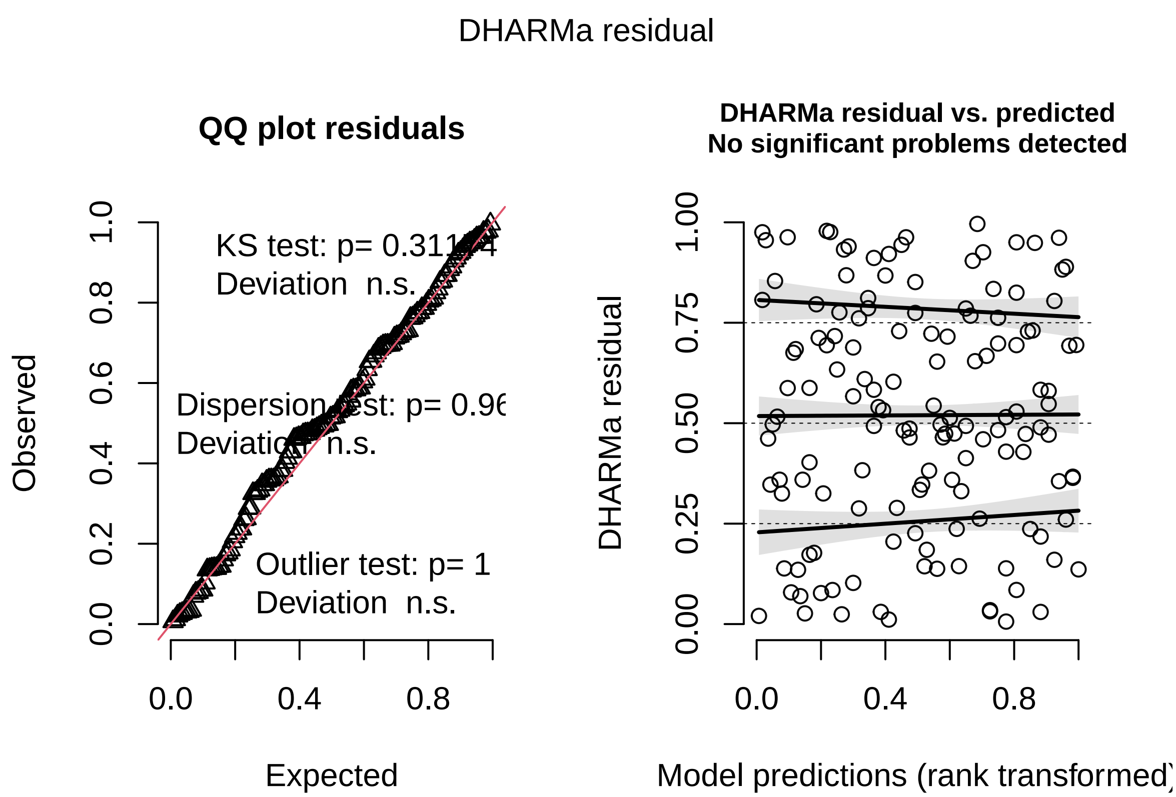


2) Plot negative binomial and check diagnostics.

- Residual plots show that there is no overdispersion and no excessive outliers. This shows that the negative binomial is a much better fit.

```
worker_lm_negbin <- glmmTMB(workers ~ nest_searching_queens_scaled +
                        bombus_floral_abun_scaled +
                        num_burrows_scaled +
                        bee_season_type,
                      family = nbinom2,
                      data = field_data
                        )

residuals_workers_negbin <- simulateResiduals(fittedModel = worker_lm_negbin, plot = TRUE)
```



```r
summary(worker_lm_negbin)
```

```

```

Findings

Number of nest-searching queens and number of rodent burrows is does not significantly effect number of workers. Significantly more workers during worker season than during nest-searching season. Marginally insignificant (p=0.0573) positive effect of bombus-relevant floral abundance on worker abundance.
